# Content

- My experiences with courses and tutorials
- Practice with real-world example (expand existing interceptor with tdd)
- First attempt (without code changes)
- Second attempt
- Conclusion

# My experiences with courses and tutorials

- Examples are simple and isolated
- They allways works
- When I try to adapt them, normally they don't work

# Practice with real-world example

- Try to use TDD with existing class
- Change interceptor to suppress log error by a certain Exception
- Exception can be placed in any cause
- Mock all around the class
- Test the main method

# Second attempt (part 1)

- Add constructor to pass mock for logger
- Test existing implementation

```
@test
void testLogger() {
    // Given
    MockLogger mockLogger = new MockLogger();
    // When
    // Act
    // Assert
}

// ...

MockLogger mockLogger = new MockLogger();
// ...
}
```

# Second attempt (part 2)

- 3 Tests with deeper nested exceptions
- Single indentation
- No elses

```
def test():
    try:
        # Test 1: nested exceptions
        try:
            try:
                raise ValueError("Test 1")
            except ValueError:
                raise RuntimeError("Test 1")
        except RuntimeError:
            raise ValueError("Test 1")
    except ValueError:
        pass

    try:
        # Test 2: nested exceptions
        try:
            try:
                raise ValueError("Test 2")
            except ValueError:
                raise RuntimeError("Test 2")
        except RuntimeError:
            raise ValueError("Test 2")
    except ValueError:
        pass

    try:
        # Test 3: nested exceptions
        try:
            try:
                raise ValueError("Test 3")
            except ValueError:
                raise RuntimeError("Test 3")
        except RuntimeError:
            raise ValueError("Test 3")
    except ValueError:
        pass
```

```
def test():
    try:
        # Test 1: nested exceptions
        try:
            try:
                raise ValueError("Test 1")
            except ValueError:
                raise RuntimeError("Test 1")
        except RuntimeError:
            raise ValueError("Test 1")
    except ValueError:
        pass

    try:
        # Test 2: nested exceptions
        try:
            try:
                raise ValueError("Test 2")
            except ValueError:
                raise RuntimeError("Test 2")
        except RuntimeError:
            raise ValueError("Test 2")
    except ValueError:
        pass

    try:
        # Test 3: nested exceptions
        try:
            try:
                raise ValueError("Test 3")
            except ValueError:
                raise RuntimeError("Test 3")
        except RuntimeError:
            raise ValueError("Test 3")
    except ValueError:
        pass
```

# Conclusion

- Sometimes it is difficult to write tests when tested classes are only a part of the system
- Environments can produce sideeffects
- Difficult to do only small steps
- Improved applying of tdd rules
